Evidence before release

A local report that shows what a software change actually proves

Release claims need evidence

A passing local test answers one question:

Did this check pass in this local environment?

It does not prove that a hosted integration works, a provider responded, or production is ready.

The risk

Teams can overstate what their tests and simulations establish.

One manifest, an evidence brief

Input

**One bounded
evidence manifest**

Calculate

**Validate evidence
and derive each
claim status**

Review

**A self-contained
JSON, Markdown, or
HTML report**

The report keeps the evidence class, limitation, and next action beside every claim.

Three outcomes stay distinct

CONDITIONAL

A passing result was declared, not run

It stays conditional until the explicit runner observes it.

SIMULATED

Synthetic fixture evidence

Simulation does not become live or hosted evidence.

UNVERIFIED

Hosted evidence is missing

The claim stays unverified until that environment is checked.

Checks run only through a fixed allowlist

Explicit action

A separate run-check command

Fixed registry ID

Known local operation

Not automatic

Report generation does not execute checks.

Unknown IDs are blocked. The demo calls no external AI provider.

Local checks are bounded; their captured output is not included in the report.

Built with IBM Bob IDE

Bob IDE

Repository-aware development partner used during the build

Proofline

Deterministic evidence classification and bounded local checks

106 local tests passed

All three synthetic states reviewed in a local browser

Redacted Bob history and summary screenshot are included in the repository.

What remains to prove

Verified locally

Manifest validation, 106-test verification, safe reports, and an allowlisted local check.

Observed in the hosted demo

A live synthetic case remained conditional; no commands ran.

Still unverified: providers, private-data protections, and production readiness.
